

Research questions:

1. How well can young adults distinguish between true and false content when it is AI-generated versus human-generated
2. How do perceived trustworthiness ratings differ between AI-generated and human-generated content
3. How does labeling content as AI-generated versus human-generated affect distinguishing between true and false content?
4. How does labeling content as AI-generated versus human-generated affect perceived trustworthiness

Independent variables:

- Statement truthfulness
 - True
 - False
- Statement source
 - AI
 - Human
- Source label visibility
 - Labeled
 - Not labeled

Dependent variables:

- Predicted truthfulness
 - True/False/I don't know
- Confidence
 - 1-7 scale
- Perceived source (only relevant when label is not shown)
 - AI - human 7-likert scale
- Trustworthiness
 - Scale 1-7

Confounding variables:

- AI literacy
- AI trust
- Education level
- General confidence
- Specialized knowledge (1-7 scale)
 - Geography and history
 - Science and health
 - Entertainment and literature
 - Technology and internet

Demographics

- Age (18-25)
- Gender
- Nationality

How would the experiment look:

Experiment A (unlabeled):

- Agent gets created with a specific persona
- I send them a statement
- Agent answers 4 questions regarding that statement:
 - Is it true or not? (T/F/IDK)
 - How confident are you in the previous answer? (1-7)
 - Is it AI or Human generated? (1-7, definitely human - definitely ai)
 - How trustworthy is it? (1-7, completely untrustworthy - completely trustworthy)
- This gets repeated for 20 randomly selected statements.

Experiment B (labeled)

- Agent gets created with a specific persona
- I send them a statement and the source (AI/human)
- Agent answers 3 questions regarding that statement:
 - Is it true or not? (T/F/IDK)
 - How confident are you in the previous answer? (1-7)
 - How trustworthy is it? (1-7, completely untrustworthy - completely trustworthy)
- This gets repeated for 20 randomly selected statements

I would then run experiment A and B many times to get the required data for analysis.

In total each one of 80 statements from the dataset will be shown an equal amount of times to keep it balanced.
